1 Compiling and Running a SNIa_ddt Flash Simulation

Donald E. Willcox

1.1 Preparing to compile Flash

First navigate to the `Flash` directory, here called `autoDDT_dens_thresh`

```
In [22]: cd ~/codes/astro/flash/autoDDT_dens_thresh
         ls
```

```
bin    LICENSE                    setup                      setup_snia_ddt.sh   t
build  obj_GradDetParamBurn  setup_alt                      setup_snia_hddt.sh
docs   RELEASE                    setup_commands               sites
lib    RELEASE-NOTES           setup_snia_ddt_htest.sh  source
```

The `sites` subdirectory contains a set of directories named according to machine host names. Each of these directories contains the file `Makefile.h` which stores the settings `make` needs to build `Flash` for that machine.

```
In [23]: cd sites
         ls
```

```

```

To get my machine host name, I'll use the `hostname` command.

```
In [25]: hostname

snia-laptop
```

The `make` settings from `eldorado.astro.sunysb.edu` are typical for a workstation or laptop like mine so I'll just copy its directory to a new directory named according to the output of the `hostname` command. The expression `$(hostname)` in `bash` evaluates the command between the parentheses and substitutes the result of that command for the expression `$(hostname)`.

```
In [27]: cp -r eldorado.astro.sunysb.edu $(hostname)
```

The previous command created a new directory called `snia-laptop`, and I can see that it contains a `Makefile.h`

```
In [28]: cd snia-laptop
         ls

Makefile.h
```

1.2 Compiling Flash

Now that I've created a directory in `sites` with the same name as my machine hostname, I can setup and compile `Flash`. First let's return to the `Flash` top-level directory.

```
In [31]: cd ~/codes/astro/flash/autoDDT_dens_thresh
         ls

bin    LICENSE                     setup                       setup_snia_ddt.sh   t
build  obj_GradDetParamBurn  setup_alt                      setup_snia_hddt.sh
docs   RELEASE                     setup_commands               sites
lib    RELEASE-NOTES            setup_snia_ddt_htest.sh  source
```

On my computer, I installed python via the Anaconda package. Using the following command, I can list the available python environments. The default environment for me, called `root` below, is python 3, but we need python 2 to setup `Flash` for compiling, so I need to switch to the `py2` environment.

```
In [32]: conda info --envs

# conda environments:
#
py2                      /home/eugene/anaconda3/envs/py2
root                  *  /home/eugene/anaconda3
```

Here I switch to the `py2` environment where `python --version` will tell me I have access to python 2. When I'm in the python 2 environment, the text `(py2)` will be printed when I execute commands, so just ignore that in the remainder of this section.

```
In [33]: source activate py2
```

```
(py2)
```

Now let's have a look at the contents of the `bash` script `setup_snia_ddt.sh`, which calls the `setup` script for `Flash`. `Flash` is capable of doing many kinds of simulations, but I'm specifically interested in a Type Ia Supernova deflagration-to-detonation transition simulation, and I tell the `setup` script to build just such a simulation by writing `SNIa_ddt` after `./setup`.

Next comes `-objdir=` that specifies the directory where `setup` will put the source code I will need to compile in order to build a `SNIa_ddt` simulation.

`-2d` specifies I want a two-dimensional domain

`-nxb` is the number of blocks in the first dimension. Blocks are just chunks of individual grid cells in the domain.

`-nyb` is the number of blocks in the second dimension.

I'm being careful to say "first" and "second" because in the above options, `x` and `y` do not imply cartesian coordinates. In fact, the next option `+cylindrical` sets up a cylindrical 2-D axisymmetric coordinate system, where the "first" coordinate is the polar radial coordinate and the "second" coordinate is the axial coordinate.

`-maxblocks=` specifies the maximum number of blocks `Flash` will assign to any given processor.

`-with-unit=Particles/ParticlesMain` tells setup to include particles in this simulation. For `SNIa_ddt`, these are passive particles (they don't interact with the simulation physics) that just get carried around, advected along the fluid flow recording the thermodynamic state of the fluid so we can do post-processing later and do detailed nucleosynthesis calculations.

```
In [35]: cat setup_snia_ddt.sh
```

```
./setup SNIa_ddt -objdir=build/object_snia_ddt -2d -auto -nxb=16 -nyb=16 +cylindric
(py2)
```

And now let's try running the setup script.

```
In [36]: ./setup_snia_ddt.sh
```

```

```

The `make` command reads the makefiles in this directory and compiles `Flash`. The `-j` option to `make` uses multiple CPU threads to parallelize the compilation. Because there are many source files, this speeds up compilation by using a set of threads to simultaneously compile multiple source files at once.

```
In [ ]: make -j
```

```

Linking in Units and Libraries
```

And we see that after compilation, the executable `flash4` is produced.

```
In [39]: ls flash4

flash4
(py2)
```

Compilation also produced a few other files that we'll need to actually run `Flash` so I made a handy `packageFlash.sh` script to bundle everything we need in a tarball. It's in the `build` directory of `Flash` and let's quickly inspect its contents using the `cat` command.

This just uses `tar` to package `flash.par`, `*.dat`, `*.txt`, and the executable `flash4` into the tarball `flashbinary.tar.gz`, compressed with `gzip`.

```
In [42]: ls ../.
         cat ../packageFlash.sh

object_snia_ddt                              objectSNIa_hddt
objectSNIaDDT                               object_snia_hddt_alan
objectSNIaDDT_Build001                       object_snia_hddt.bak
objectSNIaDDT_Build002                       object_snia_hddt_old
objectSNIaDDT_Build003_Pavel_debugging       object_snia_hddt_v2
objectSNIaDDT_Build004                       packageFlash.sh
(py2) tar -chz --file=flashbinary.tar.gz flash.par *.dat *.txt flash4
(py2)
```

Let's copy `packageFlash.sh` into the build directory and run it. It will produce the file `flashbinary.tar.gz`

```
In [43]: cp ../packageFlash.sh .
         ./packageFlash.sh
         ls *.gz
```

```
(py2) (py2) flashbinary.tar.gz
(py2)
```

Finally we don't need python 2 anymore so we can deactivate the python 2 environment by doing the following:

```
In [53]: source deactivate
```

1.3 Running Flash

Okay, now we're finally ready to run `Flash` so let's start by going to the top-level `Flash` directory, navigating to our build directory, and locating the `flashbinary.tar.gz` file we created in the previous section.

```
In [16]: cd ~/codes/astro/flash/autoDDT_dens_thresh
         ls

bin    LICENSE                      setup                       setup_snia_ddt.sh   t
build  obj_GradDetParamBurn  setup_alt                      setup_snia_hddt.sh
docs   RELEASE                      setup_commands              sites
lib    RELEASE-NOTES             setup_snia_ddt_htest.sh  source

In [17]: cd build/object_snia_ddt
         ls *.gz

flashbinary.tar.gz
```

I'm going to copy that tarball into an empty directory for running `Flash` - `~/scratch/runflash` will do just fine.

```
In [18]: cp flashbinary.tar.gz ~/scratch/runflash/.
         cd ~/scratch/runflash
         ls

flashbinary.tar.gz
```

Now I'll untar the tarball, yielding `flash4` and lots of other files the `Flash` program needs to run.

```
In [19]: tar -zxvf flashbinary.tar.gz

flash.par
cc_7e8_linear_wd_plain.dat
helm_table.dat
CONeFlameTable.txt
```

```
nse_dens_emq_table.txt
nse_pres_hmq_table.txt
SpeciesList.txt
flash4
```

The next step is to copy a model file and a parameter file into my run directory. For this example, I'm going to use the CO WD model from my hybrid paper, located in the `Flash-Star/hybrid-paper-1` repository. I'm also going to copy in the parameter file `flash.par` from realization number `001`, in the same repository.

(In the below, I'm only using the bash variables `INPUTS_DIR` and `COWD_DIR` because the jupyter notebook I'm writing this in will cut off long lines.)

```
In [37]: INPUTS_DIR=~/codes/astro/Flash-Star/hybrid-paper-1/flash-inputs
         COWD_DIR=$INPUTS_DIR/co_realizations_inputs_rhoddt7.2
         cp $COWD_DIR/400k_Tc7e8_cf-Brendan_flash.dat .
         cp $COWD_DIR/Realization_001/flash.par .
         ls
```

```
400k_Tc7e8_cf-Brendan_flash.dat                      CONeFlameTable.txt
400k_Tc7e8_co_wd_R001.dat                          flash4
400k_Tc7e8_co_wd_R001_forced_hdf5_plt_cnt_0000       flashbinary.tar.gz
400k_Tc7e8_co_wd_R001_hdf5_chk_0000                flash.par
400k_Tc7e8_co_wd_R001_hdf5_chk_0001                flash.par~
400k_Tc7e8_co_wd_R001_hdf5_part_0000                helm_table.bdat
400k_Tc7e8_co_wd_R001_hdf5_plt_cnt_0000               helm_table.dat
400k_Tc7e8_co_wd_R001.log                          nse_dens_emq_table.txt
amr_runtime_parameters.dump                          nse_pres_hmq_table.txt
cc_7e8_linear_wd_plain.dat                         SpeciesList.txt
```

For the purposes of this example, I set the maximum number of timesteps to 10 so `Flash` will stop quickly.

The parameter file `flash.par` contains all the runtime parameters `Flash` uses to determine simulation settings, which input stellar model file to use, what to name output files, when to stop the simulation, etc.

I just opened the parameter file `flash.par` in `emacs` and changed the line reading:

`nend = 999999`

to:

`nend = 10`

and saved it.

```
In [27]: emacs flash.par
```

```
(emacs:4664): Gtk-WARNING **: Allocating size to Emacs 0x34c02a0 without calling gt
```

Finally I ran `Flash` - it automatically looks for `flash.par` in the current directory and reads it to get the runtime parameters. `Flash` will initialize the simulation and begin taking timesteps to advance the hydrodynamics and other simulation physics. Since I set `nend = 10`, the simulation will stop after just 10 timesteps.

```
In [28]: ./flash4

```

I can then have a look at the new files the simulation created.

`400k_Tc7e8_co_wd_R001.dat` - contains integral quantities like total kinetic energy, total burned mass, etc. It will be important for our later analysis.

`400k_Tc7e8_co_wd_R001_hdf5_chk_0000` - a checkpoint file `Flash` creates periodically throughout the simulation: each successive checkpoint file will have a unique number at the end of the filename and `Flash` can read these files to restart a simulation at some time later than time zero if we want. This will be useful for running `Flash` in a cluster environment.

`400k_Tc7e8_co_wd_R001_hdf5_part_0000` - a particle data file, these store the thermodynamic data collected by the non-interacting tracer particles, useful for postprocessing. These get unique numbers for different time steps.

`400k_Tc7e8_co_wd_R001_hdf5_plt_cnt_0000` - a plot file, this stores data useful for plotting various quantities like density and temperature in the domain at a particular timestep. As for checkpoint and particle files, the number at the end is unique to the timestep. These files will be useful for making plots and movies showing how the explosion evolves.

`400k_Tc7e8_co_wd_R001.log` - A text log file that tells you what `Flash` is doing and is useful for debugging and getting details about the simulation.
